1 Sea Transport and the Global Economy

Wonders are many on earth, and the greatest of these
Is man, who rides the ocean and takes his way
Through the deeps, through wind-swept valleys of perilous seas
That surge and sway.

(The chorus in *Sophocles' Antigone, 422 BC*, trans. R.C. Jebb)

1.1 INTRODUCTION

Characteristics of the business

Shipping is a fascinating business. Since the first cargoes were moved by sea more than 5,000 years ago it has been at the forefront of global development. The epic voyages of Columbus, Diaz and Magellan opened the maritime highways of the world, and the same pioneering spirit brought supertankers,[1] container-ships, and the complex fleet of specialized ships which each year transport a ton of cargo for every person in the world. No business is more exciting. The great shipping boom of 2004 swept the industry from rags to riches in little more than a year, making its fortunate investors some of the wealthiest people in the world. This sort of volatility created superstars like Niarchos and Onassis, and a few villains like Tidal Marine, which built up a 700,000 dwt (dead-weight tonnage) shipping fleet in the early 1970s and were indicted with a number of their bankers for fraudulently obtaining more than $60 million in loans.[2]

Our task in this book is to understand the economics of the industry. What makes it so interesting to economists is that the shipping investors who grapple with shipping risk are so visible, and their activities so well documented, that we can blend theory and practice. For all their flamboyance, they operate within a strict economic regime, which would be immediately recognizable by nineteenth-century classical economists. It is, more or less, the 'perfect' market place at work, an economic Jurassic Park where the dinosaurs of classical economics roam free and consumers get a very good deal – there are not many monopolies in shipping! Occasionally the investors miscalculate, as in the remarkable episode in 1973 when investors in the tanker market ordered over 100 million tons deadweight (m.dwt) of supertankers, for which there turned out to be no demand.

SEA TRANSPORT AND THE GLOBAL ECONOMY

Some went from the builder's yard straight into lay-up, and few ever operated to their full economic potential. Or occasionally they run short of ships and rates go sky high, as they did during the booms of 1973 and 2004–8. But generally they 'deliver the goods' economically as well as physically at a cost which, on average, has increased surprisingly little over the years.[3]

Because shipping is such an old industry, with a history of continuous change, sometimes gradual and occasionally calamitous, we have a unique opportunity to learn from the past. Time and again we find that shipping and trade greased the slipway[4] from which the world economy was launched on new voyages in whatever political and economic vessel history had devised for it. No other industry had played such a central part in these economic voyages over thousands of years – the airline industry, shipping's closest counterpart, has barely 50 years of economic history to study! So before we plunge into the details of the shipping business as it is today, we will spend a little time studying the history of this ancient global industry to see how the economics worked in practice and where the industry is today in its latest epic voyage of globalization.[5]

The role of sea trade in economic development

The importance of sea transport in the early stages of economic development is well known to economists. In Chapter 3 of *The Wealth of Nations*, published in 1776, Adam Smith argued that the key to success in a capitalist society is the division of labour. As productivity increases and businesses produce more goods than they can sell locally, they need access to wider markets. He illustrated the point with the famous example of making pins. Working alone, ten craftsmen can produce less than 100 pins a day, but if each specializes in a single task, together they can produce 48,000 pins a day. This is far too many to sell locally, so unlocking the power of 'division of labour' depends on transport, and this is where shipping had a crucial part to play:

> As by means of water carriage a more extensive market is opened to every sort of industry than what land carriage alone can afford it, so it is upon the sea-coast, and along the banks of navigable rivers, that industry of every kind naturally begins to subdivide and improve itself, and it is frequently not until a long time after that those improvements extend themselves to the inland parts of the country.[6]

In primitive economies shipping is generally more efficient than land transport, allowing trade to get started earlier. Adam Smith paints a graphic picture of the economic benefits offered by sea transport in the eighteenth century:

> A broad wheeled wagon attended by two men and drawn by eight horses in about six weeks time carries and brings back between London and Edinburgh nearly 4 tons weight of goods. In about the same time a ship navigated by six or eight men, and sailing between the ports of London and Leith, frequently carries and brings back 200 ton weight of goods.[7]

That is a labour productivity benefit of 15 times. By exploiting economies of scale and integrated transport systems, shipping continues to demonstrate Adam Smith's insight. Today a lorry carrying one 40-foot container from Felixstowe to Edinburgh might be competing with a small container-ship carrying 200 containers. Or a truck hauling 40 tons of oil along our congested highways competes with a coastal oil tanker carrying 4,000 tons of oil by sea. Ships now travel at speeds that trucks can hardly match on congested urban roads and at a fraction of the cost. No wonder the oceans are the highways of economic development, an aspect of the business which hardly changes with the centuries. Many practical aspects of the business have not changed either. For example the bill of lading from AD 236 in Box 1.1 shows that Roman shipowners worried just as much about demurrage as shipowners do today. But new generations of shipowners also face new challenges, and shipping companies that do not adapt, however big or prestigious they may be, soon discover how ruthless the shipping market is in forcing the pace of change.

History of maritime development – the Westline

So in this chapter we are not just concerned with history. Winston Churchill said 'the further backward I look the further forward I can see',[8] and if he was right, the shipping industry is in a unique position to learn from its past about the economics of the maritime business. The evolution of sea transport is a well-travelled road which we can even plot on a map. Over 5,000 years, whether by chance or some deeply hidden economic force, the commercial centre of maritime trade has moved west along the line shown by the arrows in Figure 1.1. This 'Westline' started in Mesopotamia in 3000 BC, and progressed to Tyre in the eastern Mediterranean then to Rhodes, the Greek mainland and Rome. A thousand years ago Venice (and soon after Genoa) became the crossroads for

> ## BOX 1.1 A BILL OF LADING, AD 236
>
> This bill of lading is given by Aurelius Heracles, son of Dioscorus of Antaeopolis, master of his own ship of 250 artabae burden, without any figurehead, to Aurelius Arius, son of Heraclides, senator of Arsinoe, capital of Fayum, for the carriage of 250 artabae of vegetable seed, to be conveyed from the haven of the Grove to the capital of Arisonoe in the haven of Oxyrhynchus, the freightage agreed on being 100 clean silver drachmae, whereof he has received 40 drachmae, the remaining 60 drachmae he is to receive when he lands the cargo; which cargo he shall land safe and undamaged by any nautical mishap; and he shall take for the journey two days, from the 25th, and likewise he shall remain at Oxyrhynchus four days; and if he be delayed after that time he, the master, shall receive 16 drachmae per day for himself; and he the master shall provide a sufficient number of sailors and all the tackle of the ship; and he shall receive likewise for a libation at Oxyrhynchus one ceramion of wine. This bill of lading is valid, in the third year of Emperor Caesar Gaius Julius Verus Maximus the Pious, the fortunate, the 22nd of Phaophi (Oct. 19th).

trade between the Mediterranean and the emerging north-western European centres of Cologne, Bruges, Antwerp and Amsterdam. Meanwhile the Hanseatic towns were opening up trading links with the Baltic and Russia. The two streams merged in Amsterdam in the seventeenth century and London in the eighteenth. By the nineteenth century steamships carried the Westline across the Atlantic, and North America became a leading centre of sea trade. Finally, in the twentieth century commerce took another giant step west across the Pacific as Japan, South Korea, China and India picked up the baton of growth.

This evolution of maritime trade was led successively by Babylon, Tyre, Corinth, Rhodes, Athens, Rome, Venice, Antwerp, Amsterdam, London, New York, Tokyo, Hong Kong, Singapore and Shanghai. At each step along the Westline there was an economic struggle between adjacent shipping super-centres as the old centre gave way to the new challenger, leaving a trail like the wake of a ship that has circumnavigated the world. The maritime tradition, political alignments, ports, and even the economic wealth of the different regions are the product of centuries of this economic evolution in which merchant shipping has played a major part.

In this chapter we will try to understand why Europe triggered the expansion rather than China, India or Japan, which were also major civilizations during this period. Fernand Braudel, the French trade historian, distinguished *the* world economy from *a* world economy which 'only concerns a fragment of the world, an economically autonomous section of the planet able to provide for most of its own needs, a section to which its internal links and exchanges give a certain organic unity'.[9] From this perspective

shipping's achievement, along with the airlines and telecommunications, was to link Braudel's fragmented worlds into the single global economy we have today.

The discussion in the remainder of this chapter is divided into four sections. The first era, stretching from 3000 BC to AD 1450, is concerned with the early history of shipping, and the development of trade in the Mediterranean and north-western Europe. This takes us up to the middle of the fifteenth century when Europe remained completely isolated from the rest of the world, except for the trickle of trade along the Silk and Spice routes to the east. In the second period we start with the voyages of discovery and see how the shipping industry developed after the new trading routes between the Atlantic, the Pacific and the Indian Ocean were discovered. Global trade was pioneered first by Portugal, then the Netherlands and finally England. Meanwhile North America was growing into a substantial economy, turning the North Atlantic into a superhighway between the industrial centres of East Coast North America and north-western Europe. The third era, from 1800 to 1950, is dominated by steamships and global communications which together transformed the transport system serving the North Atlantic economies and their colonies. A highly flexible transport system based on liners and tramps was introduced and productivity increased enormously. Finally, during the second half of the twentieth century liners and tramps were replaced by new transport systems making use of mechanization technology – containerization, bulk and specialized shipping.

1.2 THE ORIGINS OF SEA TRADE, 3000 BC TO AD 1450

The beginning – the Arabian Gulf

The first sea trade network we know of was developed 5,000 years ago between Mesopotamia (the land between the Tigris and Euphrates rivers), Bahrain and the Indus River in western India (Figure 1.2). The Mesopotamians exchanged their oil and dates for copper and possibly ivory from the Indus.[10] Each river system probably had a population of about three quarters of a million, more than ten times as great as the population density in northern Europe at that time.[11] These communities were linked by land, but sheltered coastal sea routes provided an easy environment for maritime trade to develop. Bahrain, a barren
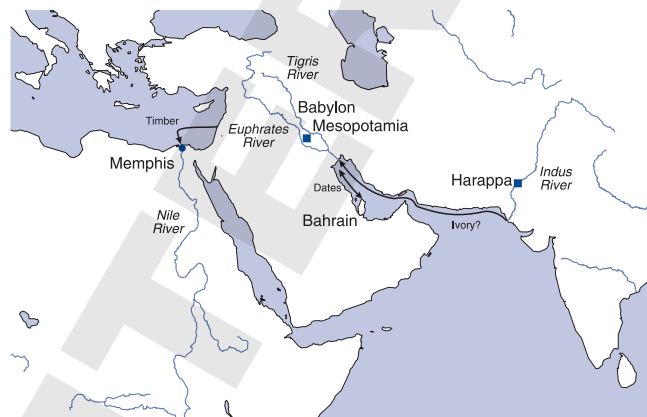

Figure 1.2
Early sea trade, 2000 BC

island in the Arabian Gulf, played a part in this trade, but it was Babylon which grew into the first 'super-city', reaching a peak in the eighteenth century BC under Hammurabi, the sixth Amorite king. By this time the Mesopotamians had a well-developed maritime code which formed part of the 3600-line cuneiform inscription, the legal Code of Hammurabi, discovered on a diorite column at Susa, the modern Dizful in Iran.[12] The Code required ships to be hired at a fixed tariff, depending on the cargo capacity of the vessel. Shipbuilding prices were related *pro rata* to size and the builder provided a one-year guarantee of seaworthiness. Freight was to be paid in advance and the travelling agent had to account for all sums spent. All of this sounds very familiar to modern shipowners, though there was obviously not much room for market 'booms' under this command regime of maritime law! About this time seagoing ships were starting to appear in the eastern Mediterranean where the Egyptians were active traders with the Lebanon.

Opening Mediterranean trade

Tyre in the Lebanon, located at the crossroads between the East and the West, was the next maritime 'super-city'. Although founded in 2700 BC, Tyre did not become a significant sea power until after the decline of Egypt 1700 years later.[13] Like the Greeks and Norwegians who followed in their steps, the poor, arid hinterland of this island encouraged its inhabitants to become seafarers.[14] Their trading world stretched from Memphis in Egypt through to Babylon on the Euphrates, about 55 miles south of Baghdad. Tyre, which lay at the crossroads of this axis, grew rich and powerful from maritime trade. The Phoenicians were shipbuilders and cross-traders (carriers of other people's merchandise) with a trade portfolio that included agricultural produce, metals and manufactures. By the tenth century BC they controlled the Mediterranean trade routes (Figure 1.3), using ships built from cedar planks, usually with a crew of four. Agricultural trades included honey from Crete, wool from Anatolia, plus timber, wine and oil. These were traded for manufactures such as Egyptian linen, gold and ivory, Anatolian wool, Cypriot copper and Arabian resins.[15]

Figure 1.3
Phoenician trade, 1000 BC

This traffic grew steadily in the first millennium BC, and as local resources were depleted they travelled further for trading goods. After the discovery of Spain and the settlement of Sades (Cadiz) around 1000 BC, the Iberian peninsula became a major source of metal for the economies of the eastern Mediterranean, consolidating Tyre's commercial domination in the Orient. On land, the domestication of camels made it possible to establish trade routes between the Mediterranean and the Arabian Gulf and Red Sea, linking with the sea trade between the Ganges and the Persian Gulf. In about 500 BC King Darius of Persia, keen to encourage trade, ordered the first Suez Canal to be dug so that his ships could sail direct from the Nile to Persia. Finally, the city of Tyre was captured by Alexander the Great after a long siege and the Phoenician mastery of the Mediterranean came to an end.

The rise of Greek shipping

By 375 BC the Mediterranean was much busier and was ringed by major towns: Carthage in North Africa, Syracuse in Sicily, Corinth and Athens in Greece, and Memphis in Egypt (Figure 1.4). As the Phoenician merchants declined, the more cen-trally placed Greeks with their market economy took their place as the leading maritime traders. As Athens expanded, the city imported grain to feed its popu-lation, one of the earliest bulk trades.[16] Two hundred years later the eastern Mediterranean had become an active trading area domi-nated by the four principal towns of Athens, Rhodes, Antioch and Alexandria. The latter two grew particu-larly strong, thanks to their trading links to the East through the Red Sea and the Arabian Gulf.

The Greeks traded their wine, oil and manufac-tures (mostly pottery) for

Figure 1.4
Mediterranean trade, 300 BC

Carthaginian and Etruscan metals and the traditional products of Egypt and the East. Initially Corinth was the leading town, benefiting from its position on the Isthmus, but subsequently Athens became more prominent thanks to the discovery of silver in nearby Laurion (c.550 BC). This paid for the navy which triumphed at Salamis, liberating the Ionians and guaranteeing safe passage to grain ships from the Black Sea on which the

enlarged city came to depend.[17] Grain and fish were shipped in from the Black Sea where, by 500 BC, Greece had founded more than 100 colonies. Carthage held most of the western Mediterranean, including the coast of North Africa, southern Spain, Corsica and western Sicily. However, this was not a developed area with less trade than the eastern Mediterranean.

Mediterranean trade during the Roman Empire

As Greece declined and Rome grew in economic and political importance, the centre of trade moved to Italy, and the Roman Empire built up a widespread trade network. Rome imported minerals from Spain, and more than 30 million bushels of grain a year from the grain lands of northern Africa, Sicily and Egypt.[18] To carry this trade a fleet of special grain ships was built. Manufactures were traded from the eastern Mediterranean and over the next 200 years the Roman Empire controlled the coasts of the Mediterranean and Black Sea, as well as southern Britain. Under the *Pax Romana,* Mediterranean trade expanded, though there were more towns and trade routes in the East than the West. The towns of the East imported minerals from the 'developing' countries of Spain and Britain, corn from North Africa, Egypt and the Black Sea, and manufactures from the still thriving commercial centres of the Lebanon and Egypt, where the eastern trade routes entered the Mediterranean. An insight into the mature commercial system employed is provided by the bill of lading from AD 236 for a cargo of seed carried up the Nile by a Roman boat (Box 1.1).

The Byzantine Empire

Towards the end of the fourth century AD the 'Westline' took a step backwards. In about AD 390 the failing Roman Empire, under attack from all sides, was split for administrative purposes into the Western Roman Empire and the Eastern Roman Empire. In modern-day jargon the Eastern Roman Empire contained the economically 'developed' world, while the Western Roman Empire, consisted mainly of 'underdeveloped' territories. The Eastern Roman Empire, with its new capital of Constantinople, grew into the Byzantine Empire, but by AD 490 the Western Roman Empire had fragmented into kingdoms controlled by the Vandals, Visigoths, Slavs, Franks, Saxons and others. Ships could no longer trade safely in the western Mediterranean, and sea trade in the West declined as Europe entered the Dark Ages. For three centuries its economy stagnated.[19]

Over the next 200 years the more stable Eastern Roman Empire, with its capital in Constantinople on the Black Sea, controlled an empire stretching from Sicily in the West to Greece and Turkey in the East. In about AD 650 its administration was overhauled, and because of growing Greek influence on its language and character it is subsequently referred to as the Byzantine Empire.[20] Gradually, by AD 700 the Arab Caliphate controlled the southern and eastern shores of the Mediterranean, and since their trade was principally by land, passage through the Mediterranean became safer. Mediterranean trade was re-established. Sea trade centred on Constantinople, which

imported corn from the Black Sea and Sicily as well as commodities such as copper and timber, with shipping routes to Rome and Venice and the Black Sea, whilst the Eastern trade by land followed the Silk and Spice routes, both through Baghdad – a clear demonstration of how much shipping and trade depend on political stability.

Venice and the Hanseatic League, AD 1000–1400

By AD 1000 the economy of North Europe had begun to grow again, based particularly on the expansion of the wool industry in England and the textile industry in Flanders. As towns grew and prospered in NW Europe, trade with the Baltic and the Mediterranean grew rapidly, leading to the emergence of two important maritime centres, Venice and Genoa in the Mediterranean and the Hanseatic League in the Baltic.

Cargoes from the East arrived in the Mediterranean by the three routes marked on Figure 1.5. The southern route (S) was via the Red Sea and Cairo; the middle route (M) through the Arabian Gulf, Baghdad and Aleppo; whilst the northern route (N) was through the Black Sea and Constantinople. The cargoes were then shipped to Venice or Genoa, carried over the Alps and barged down the Rhine to northern Europe. The commodities shipped west included silk, spices and high-quality textiles from northern Italy which had become a prosperous processing centre. The trade in the other direction included wool, metals and timber products.

In the Mediterranean, Venice emerged as the major maritime entrepôt and super-city, with Genoa as its main rival. Venice

Figure 1.5
North-west Europe opens up, 1480

was helped initially by its political independence, its island sites and the commercial links with the Byzantine Empire which was by then in economic decline, with little interest in sea trade. State legislation, which enforced low interest rates for agricultural reasons, discouraged the Byzantine merchants from entering the business and the Byzantine seafarers could not compete with the low-cost Venetians, even on internal routes. So gradually the Venetian network replaced the native Byzantine one.[21] By accepting Byzantine suzerainty

Venice was able to control the East–West trade. In return for their shipping services they procured preferential tax rates, and in 1081 they won the right to trade anywhere within the Byzantine Empire, without restriction or taxation of any kind. This was an early example of outsourcing sea transport to an independent flag. We will come across many other examples, especially in the twentieth century.

But by the beginning of the thirteenth century the epicentre of maritime trade started to move west. The weakened Byzantine Empire had lost control of Anatolia to the Seljuk Turks, and by 1200 Venice's privileged position with the Byzantine Empire was fading. But this was its peak as a maritime power[22] and as the economy of NW Europe grew, Venice and Genoa's commercial position gradually declined. The sacking of Constantinople by the Ottoman's in 1453 blocked the busy northern trade routes through the Black Sea, increasing the risks and diminishing the returns of the East–West trade. Meanwhile Bruges in Belgium was emerging as Venice's successor. It had an excellent position on the River Zwin estuary, and its monopoly in the English wool trade was strengthened when the direct sea route with the Mediterranean was opened. After the first Genoese ships put in at Bruges in 1227, trade gradually bypassed Venice and the arrival of sailors, ships and merchants from the Mediterranean brought an influx of goods and capital along with commercial and financial expertise. Bruges became the new maritime entrepôt, with a huge trading network covering the Mediterranean, Portugal, France, England, Rhineland and the Hansa ports. Its population grew rapidly from 35,000 inhabitants in 1340 to 100,000 in 1500.[23]

The other strand was NW Europe's need for raw materials to support its economic growth. Russia and the Baltic states were the primary source, exporting fish, wool, timber, corn and tallow, which was replacing vegetable oil in lamps. As this trade grew, Hamburg and Lübeck, which were at the crossroads between the NW Atlantic and the Baltic, grew prosperous and organized themselves into the Hanseatic League.

1.3 THE GLOBAL ECONOMY IN THE FIFTEENTH CENTURY

By the fifteenth century there were four developed areas of the world: China, with a population of 120 million; Japan, with 15 million; India, with a population of 110 million; and Europe, with a population of about 75 million. But the only links between them were the tenuous silk and spice routes through Constantinople and Tabriz to China, and the spice route through Cairo and the Red Sea from India.

In terms of wealth and economic development, the Chinese Empire had no rival, with a bureaucracy of indestructible traditions and a history going back 3,000 years.[24] China's seagoing expertise was also in some areas significantly ahead of Europe's. In 1403 the Ming Emperor Zhu Di ordered the construction of an imperial fleet, under the command of Admiral Zheng He. This fleet undertook seven voyages between 1405 and 1433, with over 300 ships and 27,000 men (the need to supply the ships so quickly which must have triggered quite a shipbuilding boom). Contemporary Ming texts suggest that the treasure ships were over 400 feet long with a beam of 150 feet, four times the size of European ocean-going ships, which were typically

100 feet long with 300 tons capacity, but there are doubts about whether such large wooden hulls could have been built.[25] However, the Chinese vessels were certainly technically advanced, with multiple masts, a technique only just developed by the Portuguese, and up to 13 watertight compartments. In sail technology, the Europeans still relied on square sail rigs on their ocean vessels, whilst the Chinese had been using fore-and-aft lugsails in ocean-going ships since the ninth century, giving them a great advantage when sailing upwind. During the seven voyages the great fleet visited Malaysia, the Indian subcontinent, the Arabian Gulf, and Mogadishu in East Africa, travelling about 35,000 miles. There is also some evidence that on one of the voyages the fleet sailed into the South Atlantic and mapped the Cape of Good Hope.[26]

Although by the fifteenth century Chinese mariners were ahead of Europe in some areas of ocean-going ship technology and had the ships and navigational skills to explore and trade with the world, they chose not to do so. In 1433 the expeditions were halted, the ships destroyed and laws passed banning further construction of ocean-going ships, leaving the way open for European seafarers to develop the global sea transport system we have today. What followed was a major shift in global trade as the nations of NW Europe, whose route to the East was now blocked by the Ottoman Empire, discovered the sea route round the Cape and used their naval superiority to create and control global trade routes.

1.4 OPENING UP GLOBAL TRADE AND COMMERCE, 1450–1833

Europe discovers the sea route to Asia

In just a few years in the late fifteenth century, Europe laid the foundation for a global sea trade network which would dominate shipping for the next 500 years. It is hard to imagine the impact which the voyages of discovery (Figure 1.6) must have had, penetrating the Atlantic Ocean and turning sea trade into a global business.[27] The goal was economic: to find a sea route to Asia, the source of the precious spices and silk traded along the spice and silk routes from the east. Marco Polo's 'Description of the World' published in 1298 had publicized the East as an economically attractive destination. He reported that the 'spice islands' consisted of

> 7,488 islands, most of them inhabited. And I assure you that in all these islands there is no tree that does not give off a powerful and agreeable fragrance and serves some useful purpose. There are, in addition, many precious spices of various sorts. The islands produce pepper as white as snow and in great abundance, besides black pepper. Marvellous indeed is the value of the gold and other rarities found in these islands.[28]

No wonder the fabulous 'Spice Islands' gripped the imagination of the European kings and adventurers.
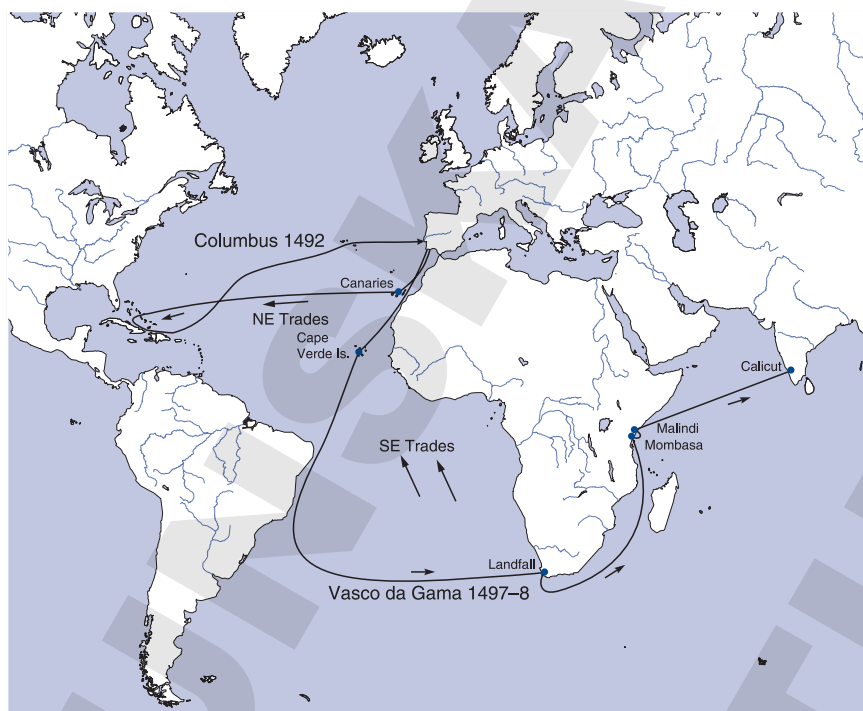

Figure 1.6
The European voyages of discovery 1492–98

The problem was getting there. The overland trade was increasingly difficult, and a map drawn by Ptolemy in the second century AD showed the Indian Ocean as being landlocked. However, information gleaned from Moorish traders who had crossed the Sahara hinted that this might not be the case. It was difficult to find out because the South Atlantic was a challenging barrier for sailing ships. Currents and winds opposed ships sailing south,[29] and there were few landfalls on the African coast between Guinea and the Cape. But by the fifteenth century the European explorers had some technical advantages, including the compass, and the astrolabe had been developed in 1480.[30] This navigational instrument allowed sailors to calculate their latitude by measuring the angle between the horizon and the Sun or the pole star, and looking up the latitude for that angle in sea tables. With it explorers could accumulate knowledge about the position of land masses they visited and gradually they built up the knowledge about the Atlantic they needed to make the journey to the east.

The Portuguese expeditions

At first progress was slow. In the early 1400s Henry 'the Navigator', King of Portugal, a small barren land with a lengthy coastline on the southern tip of Atlantic Europe,

became obsessed with finding a way around Africa.[31] His first success came in 1419 when an expedition was blown off course and discovered Madeira. Discovery of the Azores, the Canaries and the Cape Verde Islands soon followed,[32] providing the fifteenth-century explorers with a base for their voyages into the Atlantic. Another big step was taken in 1487 when the Portuguese explorer Bartholomew Diaz successfully sailed down the coast of Africa and rounded the Cape of Good Hope. However, the storms were so severe (he christened it the 'Cape of Storms', but the King of Portugal renamed it the 'Cape of Good Hope') that after making landfall just beyond the Cape his exhausted crew persuaded him to turn back, which they did, mapping the African coast as they went.

The economics of discovery

Meanwhile Christopher Columbus, a Geonese trader, seafarer and mapmaker, was planning an expedition to reach the Spice Islands by a different route. From ancient writings,[33] his own travels in the North Atlantic and intelligence from the seafaring community – including reports that trees and canes were washed up in Madeira by westerly gales[34] – he concluded that Asia could be reached by sailing west. Using the tables in *Imago Mundi*[35] he calculated that Cipangu, one of the wealthy Spice Islands described by Marco Polo, lay 2400 miles across the Atlantic.[36]

Raising funds for such a speculative scheme proved difficult. In 1480 he appealed to the Portuguese crown but the *junto* appointed to look into his scheme rejected it. However, they secretly instructed a vessel to test the theory by sailing west from Cape Verde. It was not a success and after a few days the mariners, terrified by the rough weather and the vastness of the ocean, turned back. When he heard of this duplicity Columbus left Portugal[37] and, after trying Venice, in 1485 he arrived in Spain penniless and got an audience with Ferdinand and Isabella.

After six years of procrastination Columbus's project was again rejected by the Spanish crown's advisory committee in January 1492. Then an influential courtier named Luis de Santangel took up his case. Spain had just occupied Granada, and the young nobles who had fought were expecting to be rewarded with land. Since there was not enough land in Spain, Santangel's idea was to look west as Columbus suggested. The agreement signed on 17 April 1492 appointed Columbus admiral, viceroy, governor and judge of all islands and mainlands he discovered and awarded him 10% of any treasure and spices he obtained. A royal decree was issued requiring Andalusian shipowners to provide three vessels ready for sea, and two shipping families, the Pinzons and the Ninos, finally invested in the modest expedition. Two caravels and a larger vessel set sail for the Canaries where they spent six weeks fitting out, finally setting sail for the great island of Cipangu on 6 September 1492. The NE Trades carried them across the Atlantic and at 2 a.m. on 12 October they sighted land (Figure 1.6). In reality the landfall was Watling Island (now San Salvador) in the Bahamas, but it was 20 years before anyone knew for sure that it was not the Indies.[38] Anyway there were no spices or fabulous cities, so from a trade perspective it was a false start.

The Portuguese trade network

Columbus's discovery shocked the Portuguese who had been trying to reach Asia for nearly a century, as the Spanish appeared to have found it at their first attempt. They redoubled their efforts and on 3 August 1497 Vasco da Gama set off from Lisbon with a fleet of four ships, 170 men, three months' supplies, the maps of Africa prepared by Diaz and a new navigational strategy. After calling at Cape Verde, instead of coast-hopping as Diaz had done and beating against the SE Trades, he swung south-west into the Atlantic for 10 weeks, sailing until he reached the latitude of the Cape of Good Hope, and then turned east (see Figure 1.6). It worked brilliantly, and three months after setting sail he made landfall 1° north of the Cape! A great victory for the astrolabe. Rounding the Cape, he landed at Mombasa where he was not well received, so he sailed up the coast to Malindi where he got a better reception and found a pilot. Twenty-seven days later, in May 1497, he arrived at Calicut in India, 9 months after leaving Lisbon.

Although the voyage was a success, the trade was not. After a lavish welcome by the Zamorin of Calicut, things went downhill fast. Diaz's modest gifts were ridiculed by the wealthy Calicut merchants, who had no intention of sharing their business with impoverished adventurers. Da Gama scraped together a cargo by selling his trade goods at a fraction of their cost in Portugal and bought cloves, cinnamon and a few handfuls of precious stones.[39] Discouraged, they careened their ships in Goa and headed back. The return voyage took a year and they limped back to Portugal in August 1499 with only 54 of the 170 who had set out with the expedition. But the welcome was tumultuous. The trade route was established and although the cargo was sparse, da Gama brought an invaluable piece of commercial information. The hundred-weight of pepper sold in Venice for 80 ducats could be purchased in Calicut for 3 ducats! All that was needed was to eliminate the Muslim grip on the trade and build a new commercial empire.

The Portuguese set about doing this. Six months later an expedition of 13 ships and 1300 men was despatched under Pedro Alvares Cabral to set up a depot, so that spices could be purchased and stored, ready to load when ships arrived. This time they reached Calicut in just 6 months and their lavish gifts impressed the Zamorin, who signed a trade treaty. However, after only two ships had been loaded the resentful Moslem traders rioted and stormed the depot, killing most of the staff. Cabral retaliated by bombarding Calicut, setting fire to part of the city, then moved on to Cochin where he set up a new trading post and depot, with a garrison, before returning to Portugal. Although he had lost half his ships and men, the voyage was tremendously profitable and the basis of the Portuguese trading empire had been laid. Over the next decade the Portuguese established strongholds on the East African coast and in 1510 seized the town of Goa which grew into a thriving community of 450 settlers. A year later they took Malacca, now in Malaysia, a vital spice emporium, and Hormuz on the doorstep of the Persian Gulf. The trickle of trade between East and West turned into a torrent, as cargo ships, each carrying a few hundred tons of cargo, plied the new trade route around the Cape of Good Hope.

New directions in European trade

In less than a decade Europe had established sea routes to every part of the globe and set about turning these discoveries to its advantage. Most trade in medieval Europe was in local goods, and trading opportunities were limited by the rather similar climate and technology of these countries. The voyages of discovery opened new markets for European manufactured goods and new sources of raw materials such as wool, dyestuffs, sugar, cotton, tea, coffee and of course the much sought-after spices. Over the next century the European explorers, with their improving navigational techniques and superior weapons, set about developing these trades.[40] The Cape route to the Spice Islands had an immediate commercial impact, but the Americas, which were more easily reached from Europe by exploiting the Trade winds, added a completely new dimension to the trade revolution that was taking place. These were sparsely populated territories, rich in raw materials, and provided an endless source of trade goods, a market for European manufactures, and near-perfect conditions for economic development. Over the next 200 years the trading triangle shown in Figure 1.7 developed in the North Atlantic. Manufactures were shipped from Europe to West Africa and slaves to the West Indies, the ships returning with sugar, rum, tobacco and cotton.

Figure 1.7
Sea trade in the eighteenth century

Trading in this enlarged world economy made NW Europe rich, and the new wealth soon produced a flourishing financial system with joint stock companies, bourses (stock exchanges), central banks and insurance markets. It also transformed the shipping business. Transport was still expensive (coal in London cost five times as much as it did at the pit head in Newcastle), and shipping was mainly an archaic business 'where the men who built the boats themselves loaded goods on board and put to sea with them, thus handling all the tasks and functions occasioned by maritime trade'.[41] Much more was needed to develop the new world economy. Deep-sea trade needed bigger ships, capital to finance the long voyages, and specialization.

The rise of Antwerp

Although Portugal developed the important eastern trade, and Spain the Americas, the next maritime capital was not Lisbon or Seville, but Antwerp on the River Scheldt. Situated at the heart of the new overseas trading network and benefiting from an inland trade network built up during the Hapsburg occupation of the Low Countries, it became the most important market place for the rapidly developing global trade. In the late fifteenth century Antwerp had started to take over the distribution of Venetian cargoes from Bruges, whose harbour was silting up, and in 1501 the first Portuguese ship laden with Indian pepper, nutmeg, cinnamon and cloves berthed in Antwerp. It was a logical step for the Portuguese who were carrying the huge cost of sending ships to the Indies, and preferred to leave the wholesale distribution to the established Antwerp merchants who already handled the Venetian trade. Other trades followed. English merchants traded English cloth and wool; the southern German bankers (Fuggers, Welsers) traded cloth, spices and metals with Germany and Italy, while Spanish merchants from Cadiz brought cargoes of wool, wine and silver, with backhaul cargoes of cloth, iron, coal and glass. By 1520 Antwerp had become the market place for trade with the Mediterranean and the East.[42]

Antwerp also grew into a financial centre. The money market which it created between 1521 and 1535 played a major part in financing the Spanish development of the Americas. Merchants became expert at such capitalist techniques as double-entry bookkeeping, joint-stock companies, bills of exchange, and stock markets.[43] The efficiency of this new society was apparent in its most essential aspect – shipping. In 1567 Luigi Guicciardini counted 500 vessels moored before the roadstead in Antwerp and was impressed by the mighty crane on the wharf.[44]

However, Antwerp's dominant position as the leading maritime centre was short-lived. In 1585 the city was sacked by Spanish troops and the Scheldt was blocked by the Dutch. Many of the merchants fled to Amsterdam, which rapidly took over as the maritime capital.

Amsterdam and the Dutch trade

Amsterdam's advantage was both geographical and economic. Its location as a maritime centre was excellent, with the Zuider Zee providing superb protected access for big

ships, though it was difficult to navigate. It also had the support of the whole Dutch seaboard open to maritime trade, and between 1585 and 1620 took over from Genoa in the South and Antwerp in the North as the centre of a network of sea trade stretching from the Baltic to India. By 1701 a French guide reported 8,000 ships in Amsterdam harbour 'whose masts and rigging were so dense that it seems the sun could hardly penetrate it',[45] and the Amsterdam Gazette reported dozens of boats leaving and arriving every day. The Dutch fleet was estimated in 1669 to consist of 6,000 ships, of roughly 600,000 tons, the equivalent of all the other European fleets put together.[46]

However, the commercial advantages of the Dutch entrepreneurs should not be overlooked. As the Dutch became the entrepreneurs, merchants, bankers and 'cross-traders' of the newly emerging global trade there was much talk of the 'Dutch miracle'. This small, bare country had a population of about 1 million in 1500, half living in towns, far more than elsewhere in Europe, and they were 'so given to seafaring that one might think water rather than land their element'.[47] Dutch shipping's success owed much to their low costs, at least a third less than anyone else. To carry the growing bulk trade the Dutch developed an ocean-going merchantman, the *fluyt* or 'flyboat'. These vessels had 20% more cargo capacity and needed only seven or eight crew on a 200-ton vessel, compared with 10 or 12 on an equivalent French boat. The Dutch also had a very competitive shipbuilding industry[48] and a thriving sale and purchase market for second-hand ships.[49] With the cheap freight rates provided by the flyboat, the Dutch expanded in the bulk trades in corn, timber, salt and sugar. One great success was the Baltic grain trade, which increased rapidly as the growing population of NW Europe created a demand for imports.

By 1560 the Dutch had three-quarters of the Baltic bulk trade,[50] trading grain, forest products, pitch, and tar. Amsterdam became 'the corn bin of Europe'. Next they opened trade with the Iberian peninsula, trading wheat, rye and naval stores for salt, oil, wine and silver. Amsterdam's position as a financial centre developed with the opening of the Bourse (stock exchange), and with their lower costs they were able to squeeze out the northern Italian merchants, whose strategic position was already weakened.[51] Venetian ships had stopped sailing to the Netherlands, and 50 years later the Mediterranean to North Europe trade was being serviced by English and Dutch vessels, with half the Venetian fleet being built in Dutch shipyards.

However their greatest success was in the East where, after a slow start, they established a dominant position. Initially the Dutch merchants made little headway against Portuguese, English and Asian merchants. They needed large ships for the long voyages, fortified trading posts and military strength to deal with local opposition from natives and other traders. Individuals could not capitalize ventures on this scale, and their solution was to set up a company to provide capital and manage the trade. The Dutch East India Company was founded in 1602 with capital of 6,500,000 florins raised from the public. Its charter permitted it to trade 'westward into the Pacific from the Straits of Magellan to the Cape of Good Hope' with total administrative and judicial authority.[52] This strategy was very successful and the company rapidly grew in influence, obtaining a monopoly in the trade with Malaysia, Japan and China.

By 1750 Amsterdam's position as an entrepôt was waning as more trade went direct and the industrial revolution moved the hub of maritime trade to Britain. The steam engine made it possible to use coal to power machinery and as machines replaced people in manufacturing, the output of goods increased. The most immediate application was in that staple of international trade, textiles. Over the next 50 years, British manufacturers automated all the most skilled and time-consuming aspects of textile manufacture, radically reducing the cost of cotton cloth. After Hargreaves invented the 'spinning jenny', a machine for manufacturing cotton thread, the price of cotton yarn fell from 38 shillings per pound in 1786 to under 10 shillings per pound in 1800. Arkwright's water frame (1769), Crompton's 'mule' (1779) and Cartwright's power loom extended the automation to cloth manufacture. By 1815 exports of cotton textiles from Britain accounted for 40% of the value of British domestic exports.[53] New raw materials were introduced. The two most important were coal, which freed iron makers from the dependence on forests for charcoal, and cotton, which opened up a new market for clothing.

Sea trade in the eighteenth century

Sea trade, dominated by textiles, woollen cloth, timber, wine and groceries, grew rapidly and British foreign trade (net imports and domestic exports) grew from £10 million in 1700 to £60 million in 1800.[54] As the century progressed the character of imports changed. Semi-tropical foodstuffs and raw materials from the Americas appeared and after 1660 London, with its growing exports of manufactures and range of financial and shipping services, gradually moved into a leading position.[55] The long-haul Asian trade was still controlled by the English and Dutch East India Company monopolies, but the Atlantic trade was served by small traders operating in the Baltic, the Mediterranean, the West Indies, East Coast North America, and sometimes West Africa and Brazil. An idea of the size of these trades and the number of ships in them is given by the statistics of ships entering and cleared for foreign trade in Great Britain in 1792 (Table 1.1).

The trade with the Baltic, Germany, Poland, Russia and Scandinavia was one of the biggest. In 1792, 2700 ships entered Britain carrying shipbuilding materials, hemp, tallow, iron, potash and grain. Much of this trade was carried in Danish and Swedish vessels. If the ships performed three voyages a year, which seems likely given that little winter trade was possible in these northerly waters, a thousand ships would have been needed to service this trade. An equally important trade for merchants was the West Indies. Colonial produce, including sugar, rum, molasses, coffee, cocoa, cotton and dyes, was shipped home, whilst some vessels performed a triangular voyage, sailing to the Guinea Coast to pick up slaves for transport to the West Indies. In 1792 between 700 and 900 ships were employed in the trade.[56] London, Liverpool and Bristol were the chief ports in the West Indies trade. Trade with the United States employed about 250 British vessels, with an average size of around 200 tons, carrying outward cargoes of British manufacturers and re-exports of Indian and foreign products and returning with tobacco, rice, cotton, corn, timber and naval stores. There was also an active trade with British North America and Newfoundland to supply the needs of the fishermen in Hudson's Bay.

Table 1.1 British ships entered and cleared in foreign trade, 1792

	Number of ships			%	Average Tonnage
	Entered	Cleared	Total		
Baltic trades[a]	2,746	1,367	4,113	27%	186
Holland and Flanders	1,603	1,734	3,337	22%	117
France	1,413	1,317	2,730	18%	126
Spain, Portugal	975	615	1,590	10%	126

Shorter-haul trades with Spain, Portugal, Madeira and the Canaries provided employment for around 500 or 600 small vessels carrying wine, oil, fruit, cork, salts, and fine wool from Spain. There was also a long-distance trade to Greenland and the South Sea whale fisheries. Whaling was an extremely profitable industry with about 150 ships sailing annually for the whaling grounds from English and Scottish ports. Finally, there was the coasting trade. A fleet of small vessels of about 200 tons plied the east coast between the Scottish ports and Newcastle, Hull, Yarmouth and London carrying coal, stone, slate, clay, beer and grain. These were the ships that Adam Smith used to illustrate the efficiency of sea transport in *The Wealth of Nations*. Coal was by far the most important cargo, by the late eighteenth century employing around 500 vessels, of around 200 tons, making eight or nine round voyages a year.

Finally, there was the passenger trade. In addition to cargo, many of the merchant ships in the Atlantic carried a few passengers for a price agreed with the master. Most passengers, however, travelled by the Post Office packets, fast-sailing vessels of about 200 tons which carried the mail weekly to Spain, Portugal and the West Indies and at longer intervals to Halifax, New York, Brazil, Surinam and the Mediterranean. In 1808 there were 39 Falmouth packets, carrying 2,000–3,000 passengers a year. As the fare from Falmouth to Gibraltar was 35 guineas (£36.75), the command of a packet was a profitable job.

The rise of the independent shipowner

In the late eighteenth century the Atlantic trade was still mainly controlled by merchants and private partnerships. A syndicate would build or charter a ship, provide it with a

cargo, and take their profit from trade or by carrying freight for hire. A 'supercargo' generally travelled with the ship to handle the business affairs, though this was sometimes left to the master, if he was qualified. The supercargo bought and sold cargoes and could, for example, order the vessel to a second port of discharge, or to sail in ballast to a port where a cargo might be available. As trade increased, this speculative approach gradually gave way to a more structured system, with some companies specializing in the trade of specific areas like the Baltic or the West Indies and others in the ownership and operating of ships, so the roles of trader and shipowner gradually grew apart.

Some voyages undertaken by Captain Nathaniel Uring in the early eighteenth century illustrate how the trading system worked in practice.[57] In 1698 he loaded groceries in Ireland and sailed to Barbados where he sold them and purchased rum, sugar and molasses for the Newfoundland fishermen, from whom he intended to purchase a cargo of fish for Portugal. However, when he reached Newfoundland, the market was overstocked with colonial products and fish prices were so high that he sailed back to Virginia where he sold his cargo and bought tobacco. On another voyage in 1712, in the 300-ton *Hamilton*, he was instructed to load logwood at Campeachy, to be sold in the Mediterranean. He called first at Lisbon, where he sold 50 tons of logs and filled up with sugar for Leghorn (Livorno) in Italy. At Leghorn he consulted the English consul as to the respective advantages of Leghorn and Venice as markets for logwood, finally selling the cargo at Leghorn, where he entered into a charter party to carry 100 tuns of oil at Tunis for Genoa. When he arrived in Tunis the Bey compelled him to make a short coastal voyage to fetch timber from Tabarca, after which he loaded the oil and, seeing no bargains about, he filled the ship with 'other goods I could procure upon freight' for Genoa. In Genoa he contracted 'For the freight of a lading of wheat, which I was to carry first to Cadiz, and try the market there; and if that did not answer, to proceed to Lisbon'. But the winds were unfavourable for entering Cadiz, so he sailed direct to Lisbon. After delivering the wheat and 'finding the ship perfectly worn-out with age' he then sold it to Portuguese shipbreakers 'as I was empowered to do'. Quite a voyage!

Uring was both a trader and a carrier, but by the end of the century the distinction between the shipowning and trading interests was becoming clearer. The term 'shipowner' first appeared in the shipping registers in 1786,[58] and early nineteenth-century advertisements for the General Shipowner's Society laid special emphasis on the fact that their members' business was confined to running ships, with no outside interests.[59] This change was accompanied by a rise in the numbers of shipbrokers, marine underwriters and insurance brokers, whose business was involved with shipping. In 1734 *Lloyd's List* was published as a shipping newspaper, primarily for marine underwriters, and soon afterwards in 1766 Lloyd's Register of Shipping published shipping's first register of ships.[60]

Although the transport system was improving, the ships and the standards of navigation remained so inefficient that sea passage times were very long. For example, Samuel Kelly recorded that in the 1780s the voyage time from Liverpool to Philadelphia took between 43 and 63 days, whilst the return voyage from Philadelphia to Liverpool took between 29 and 47 days. Similarly, the trip from Liverpool to Marseilles was 37 days. His worst experience was a winter passage from Liverpool to New York, which took 119 days.[61] The ships were generally around 300–400 tons in size, though the East India

Company operated a fleet of 122 vessels averaging 870 tons. This unsatisfactory state of affairs was about to change.

1.5 LINER AND TRAMP SHIPPING, 1833–1950

Four innovations transform merchant shipping

In the nineteenth century shipping changed more than in the previous two millennia. A Venetian master sailing into London in 1800 would soon have felt at home. The ships were bigger, with better sails, and the navigation techniques had improved, but they were still wooden sailing ships. A century later he would have been in for a shock. The river would have been crammed with enormous steel ships, belching steam and sailing against wind and tide in response to instructions cabled across the world. In a few decades shipping was transformed from a loose system run by traders like Captain Uring to a tightly run industry specializing in the transport of cargo by sea.

This transformation was part of the industrial revolution taking place in Great Britain and Europe at this time. As manufacturing productivity increased, especially in textiles, output could not possibly be consumed locally and trade became a necessary part of the new industrial society. The engineering technology which transformed textile manufacturing also produced a new transport system to carry the manufactures to new markets and to bring in the raw materials and foodstuffs that the growing industrial population required. Many factors contributed to this change, but four were of particular importance: first, steam engines which freed ships from dependence on the wind; second, iron hulls which protected cargo and allowed much larger vessels to be built; third, screw propellers which made merchant ships more seaworthy, and fourth, the deep sea cable network which allowed traders and shipowners to communicate across the world.

As canals, railways and steamships merged into a global transport network, in the second half of the nineteenth century the shipping industry developed a completely new transport system which raised transport speed and efficiency to new heights. This new system had three parts: 'passenger liners' which transported mail and passengers on regular services between the economic 'hubs' of North America, Europe and the Far East; 'cargo liners' which transported cargo and some passengers on a widespread network of regular services between the developed and imperial markets; and the tramp shipping business which carried 'spot' cargoes on routes not served by liner services, or when cargo became available and they could offer cheaper freight.

Growth of sea trade in the nineteenth century

The scale of the change is illustrated by the speed of trade growth. Sea trade increased from 20 million tons in 1840 to 140 million tons in 1887, averaging 4.2% per year (Table 1.2). Ton miles also increased as the trades with the Baltic and the Mediterranean were

The statistics are not precisely comparable and only provide a rough idea of trade developments over this long period.

replaced by long-haul trades with North America, South America and Australia. For the first time industrial cargoes appeared on the market in very large quantities, the most important being the coal trade. For many years coal had been shipped from the north-east of England as a domestic fuel, but in the nineteenth century large quantities started to be used by industry and as bunkers for steamships. The tonnage of trade increased from 1.4 million tons in 1840 to 49.3 million tons in 1887. During the same period the trade in textile fibres, notably cotton, wool and jute also grew rapidly to supply the new textile industries of industrial Britain. After the repeal of the Corn Laws in 1847, the grain trade increased from 1.9 million tons in 1842 to 19.2 million tons in 1887. Initially the trade came from the Black Sea, but as railways opened up North and South America, the trades with the US East Coast, the Gulf and South America, especially River Plate, became equally important. Timber and the trades with the Baltic also grew and in 1887 we see the first petroleum cargoes, just 2.7 million tons, the beginning of a trade which in due course would reach over 2 billion tonnes.

   In addition to cargo, as global trade developed so did passenger traffic and mail and there was tremendous commercial pressure to speed up these services. With a 60-day round-voyage time on the North Atlantic, doing business was difficult and there was a market for fast transit. The passenger trade was also swelled by emigrants from Europe to the USA and Australia. Numbers increased from 32,000 a year between 1825 and 1835 to 71,000 a year between 1836 and 1845, and 250,000 a year between 1845 and 1854, following the 1847 California gold rush. Although this pace was not continued, the trade remained brisk until the 1950s.

Steam replaces sail in the merchant fleet

As the nineteenth century progressed, steamship technology improved dramatically. In the first half of the century sail set the pace and competition between shipyards in Britain and the United States produced some of the most efficient merchant sailing ships ever built. Until the 1850s the fledgling steamships could not compete, mainly because the engines were so inefficient. For example, in 1855 the 900 dwt steamship shown in Table 1.3 burnt 199 lb of fuel per thousand ton miles at 7.5 knots. On an Atlantic crossing it would use 360 tons of coal, occupying 40% of its cargo space. As a result, steamers were still too inefficient to be economic on deep-sea routes (see Table 1.3) and in 1852 only 153 were listed in *Lloyd's Register.*[62] But by 1875 the steam engines were using only 80 lb per thousand cargo ton miles and for the first time the shipbuilders were offering steamships well able to compete with sail in the deep sea trades.[63] The opening of the Suez Canal in 1869 was well timed to generate a surge of investment innovation, trebling the world merchant fleet from 9 m.grt in 1860 to 32 m.grt in 1902 (Figure 1.8).

   The 650-ton *John Bowes*, built in Jarrow in 1852 for the coastal coal trade, and one of the first modern bulk carriers, demonstrates the way the new technology, when used in the right trade, increased transport efficiency (see Section 6.2 and, in particular, Table 6.1). On her first trip she loaded 650 tons of coal in four hours; in 48 hours she

Table 1.3 Fuel consumption of typical cargo ships

Year built	Gross registered tonnage	Dead weight tonnage	Cargo tons	Speed knots	Engine type	Horse-power	Fuel type	Tons per day	Cargo	lb fuel/ 1,000 ton miles
1855	700	900	750	7.5	Steam 1	400 ihp	coal	12	63	199.1
1875	1,400	1,900	1,650	8.5	Steam 2	800 ihp	coal	12	138	79.9

arrived in London; she took 24 hours to discharge her cargo; and in 48 hours she was back in the River Tyne.[64] Compared with the five weeks taken by a sailing ship, this five-day round trip increased productivity by 600%. In addition to speed and reliability, the iron hulls were more consistently water-tight, reducing cargo damage, and the cargo payload was 25% bigger than a wooden ship. By 1875 a 'Handy' vessel had increased to 1400 grt (1900 dwt), and by the end of the nineteenth century ships of 4600 grt were common-place. This phase of technical progress peaked in the early decades of the twentieth century with high-speed ocean liners like the 45,000 grt *Aquitania*, built in 1914 to carry passengers and cargo between North Europe and North America. Passenger traffic had become a central feature of the maritime trade, not just for the big passenger liner operators, but also for the cargo liners and even some tramps.

But despite their productivity advantage, steamships were so expensive to build and operate that the transition from sail to steam took over 50 years. In 1850, 2,000 grt fast clippers could easily compete with the early steamships which burned so much coal that there was little cargo space on long voyages. Triple expansion steam engines solved this problem, and between 1855 and 1875 fuel consumption fell 60% from 199 pounds per thousand cargo ton miles to 80 pounds, and by 1915 it had halved again (see Table 1.3). In 1915, a 5300 grt cargo tramp used only 35 tons of coal per day and consumed only 40 pounds per cargo ton mile. Steel hulls allowed bigger ships to be built, and the opening of the Suez Canal in 1869 shortened the vital sea route between the East and Europe by 4,000 miles, with plenty of bunkering stations, giving the steamships a major advantage. With each step forward in steam technology the economic pressure on sailing ships increased, but they proved surprisingly resilient in long-haul bulk trades such as wool, rice, grain, nitrates and coal. For example, in 1891 there were still 77 sailing vessels in

Sydney loading wool for London and the last merchant sailing ship, the *Elakoon*, was not converted to motor power until 1945. There were other technical changes along the way, though none so fundamental. The first deep sea diesel-powered ship, the *Selandia,* went into service in 1912, and over the next 50 years the diesel engine replaced the steam engine, except in the most powerful ships. In the 1930s welding started to replace rivets in hull construction, and in the 1970s automation halved the number of crew required to staff a deep sea vessel.

During the next 50 years a steady stream of specialized ships were developed to carry particular types of cargo (see Figure 1.8): the *Agamemnon*, the first cargo liner in 1866; the first reefer in 1880; the first tanker, the *Glückauf* in 1886; the first diesel ship in 1912; and the first ore-oiler in 1921. However, the passenger liners were the outstanding development of this era. These vessels, designed to carry passengers and mail at great speed across the Atlantic and the Imperial routes, first appeared in the second half of the nineteenth century and reached their peak immediately before the First World War, reducing the Atlantic crossing from 17 days to five and a half days in the process (see Table 1.4).

Deep-sea cables revolutionize shipping communications

Of equal importance in transforming the shipping industry in the nineteenth century was the undersea cable network linking the continents. Until the 1860s international communication was by letter and little was heard of a ship until she returned, the 'Supercargo' or the master being relied upon to attend to business.[65] Ships could sit for weeks waiting for a return cargo. Businesses needed better information about the availability of ships and cargoes and invested heavily in trying to achieve this. In 1841, P&O introduced a fast mail service to India, sailing to Suez by sea, crossing the isthmus by camel staging posts, and then on to India by sea.[66] This allowed a bill of lading to arrive in India ahead of the cargo. Then in 1855 the first Atlantic cable was laid. The signal was feeble and after 40 days it stopped working, but it showed what could be done. A land cable across Siberia to Bombay was opened in 1865 but messages took 10 days to pass along the staging posts.[67]

Then in the 1865 the first successful transatlantic cable[68] was laid by the *Great Eastern*, Brunel's 18,915 grt iron steamship. It could manoeuvre more effectively than the sailing ships used in 1855 and was big enough to carry a cable long enough to stretch from Ireland to Newfoundland, with a mechanism to control the cable as it was paid out. On the first expedition in 1865 the cable parted in mid-ocean, and was lost along with $3 million of its investor's money, about $180 million in today's terms.[69] However, in 1866 it laid a new cable and retrieved and repaired the 1865 cable. Within a decade a network of cables linked the major cities of the world[70] and, by 1897, 162,000 nautical miles of cable had been laid, with London at the heart of the network.[71] This communications network transformed the shipping business, for the first time allowed transport to be planned. So in the end Brunel's commercial 'white elephant', the *Great Eastern*, made a far greater contribution to shipping as a humble cable layer than it could possibly have done carrying passengers.

SEA TRANSPORT AND THE GLOBAL ECONOMY

Table 1.4 Evolution of Atlantic liners, 1830–1914

Name	Length (feet)	Gross tonnage	Indicated horse power	Knots per hour	Consumption tons/day	Hull material	Propulsion system	Engine design	Built	Transit days

The liner and tramp shipping system emerges

The steamships and the communications revolution set the scene for a new and more sophisticated shipping system. As trade grew, and the complexity of the transport operation increased, the market gradually divided into three segments: passenger liners, cargo liners and tramp shipping. The basic model is illustrated in Figure 1.9. The range of cargoes being shipped by sea in the mid- to late nineteenth century is shown at the top of the diagram and included bulks, liquids, general cargo, passengers and, later in the century, refrigerated cargo. Passengers were the cream cargo which was most sought after, and one segment of the business, the passenger liners, was designed to provide fast transport on the busy routes across the Atlantic and to the Far East. The passenger

liners built for these trades were fitted with passenger accommodation and were usually relatively fast, operating to a published schedule. Cargo liners also operated on regular schedules and were often designed for specific routes. Typically they had several decks to allow them to load and discharge cargo in many ports, and they would often have provision for specialist cargoes such as refrigerated cargo and heavy lift. Finally, the tramps carried bulk cargoes such as coal and grain on a voyage by

Figure 1.9
The liner and tramp shipping system, 1869–1950

voyage basis. They were usually of a very basic design, often with just a single 'tween deck and an economical speed and cargo-handling gear. However, some were sufficiently versatile to carry general cargo and be chartered by liner companies when they were short of capacity, and the more sophisticated tramps were designed with this in mind.

The passenger liner services

Once reliable steamships were available, travel between regions became far more manageable and a network of passenger liner services rapidly developed. Initially the focus was on speed to carry mail and passengers between the continents, and the North Atlantic was the showpiece for the development of nineteenth-century shipping technology. Early liner services used sailing ships and the competition stimulated efficiency. In 1816 the Old Black Ball Line, the first liner service, was set up by Isaac Wright, a US owner. Using much-admired American sailing clippers, it offered fortnightly departures between New York and London, in competition with the Swallowtail Line, a New Bedford company. Although a great improvement, over the first 10 years the transit still averaged 23 days from New York to Liverpool and 43 days from Liverpool to New York.[72] Eventually they carried a thousand passengers a week, but by the 1850s they were eclipsed by the screw steamers of Great Britain which reduced the transit time to less than 10 days in each direction (see Table 1.4).[73]

As the century progressed the 'passenger liners' evolved into big, fast, luxurious ships with limited cargo capacity, built for the fast transport of passengers and mail and the important emigrant trade from Europe to the USA.[74] The improving technology of

ships used on the North Atlantic is demonstrated in Table 1.4, which shows that between 1833 and 1914 every aspect of ship design changed. The hull grew from 176 ft to 901 ft, and gross tonnage from 137 tons to 45,647 tons. Hull construction switched from wood to iron in the 1850s, and from iron to steel in the 1880s, whilst paddle propulsion was replaced in the 1850s by screws driven by steam engines. Triple expansion steam engines arrived in the 1880s and turbines from 1900. Speed increased from 7 knots per hour in 1833 to 25 knots per hour in 1907, and fuel consumption from around 20 tons a day to 1,000 tons a day, with a significant improvement in thermal efficiency.

Cunard developed steamships for the North Atlantic capable of offering speed and reliability in all weathers. These services were obviously highly valued by businesses. For example, when Cunard's 1156 grt paddle steamer *Britannia* was frozen in Boston harbour in 1843–4, local merchants paid for a seven-mile channel to be cut to get her out.[75] The *Britannia* had a speed of 8.5 knots on 31.4 tons of coal a day, but 30 years later in 1874 the 4566 grt *Bothnia* had a speed of 13 knots on 63 tons a day and capacity for 340 passengers, in addition to 3,000 tons of cargo (Table 1.5). By the early twentieth century these passenger liners had evolved into sophisticated vessels. The 25 knot, 31,938 grt *Mauretania,* with its 350 stokers and 1,000 tons per day bunker consumption probably used more fuel than any ship ever built. However, not all passenger liners were so exotic. The *Balmoral Castle*, built in 1910 for the South Africa trade, was a four-deck ship of 13,361 gross tons, with two quadruple expansion engines of 12,500 ihp and a more modest speed of 17.5 knots. It could carry 317 first-class, 220 second-class and 268 third-class passengers.

The companies in this business, such as Cunard, White Star, North German Lloyd, and Holland America Line, were household names and their ships were symbols of national engineering prowess. From the 1880s onwards there was much latent competition for the transatlantic speed record, the Blue Riband, and it was probably this as much as commercial considerations which led to the construction of the most extreme ships such as Hamburg America's *Deutschland* (which suffered extreme vibration), North German Lloyd's record-breaking *Kaiser Wilhelm II*, and Cunard's turbine driven sister ships *Mauritania* and *Lusitania*.

The cargo liner services

The rapidly growing trade in manufactures and raw materials across the Atlantic and between the European states and their empires in the Far East, Oceania, Africa and South America created a demand for fast, cheap and regular cargo transport services. To deal with this the shipping industry developed a sophisticated system of cargo liner services using ships designed to transport the complex mix of passengers, mail and cargoes appearing as the international economy grew in the nineteenth century, supported by a fleet of tramp ships which carried the bulkier cargoes and supplemented the liners when the need arose (see Figure 1.9). They were the backbone of world trade, providing a reliable and flexible outward transport for general cargo, and often returning with a bottom cargo of logs, copra, grain and other minor bulks, topped up with passengers and whatever specialist cargoes they could pick up. As an economic solution to a complex problem the system worked well for a century and was every bit as revolutionary as containerization in the twentieth century.

From the 1870s onwards a network of liner services spread across the world, especially between Europe and its colonies, served by a new generation of steam cargo liners. These vessels were less elaborate and slower than the passenger liners. They were built for moderate speed, with several decks for stacking general cargo, bottom holds where bulk cargoes could be stowed on the return voyage, and special features such as refrigerated holds and deep well tanks for oils. There was often accommodation for some passengers. For example, the 6690 dwt *Ruahine* (1891) had accommodation for 74 first-class, 36 second-class and 250 emigrants. However, by the end of the century many cargo liners did not carry a Board of Trade Passenger Certificate. Vessel size gradually increased, as illustrated by the Ocean Steam Ship Company fleet. The 2200 grt *Agamemnon,* built in 1865, was 309 ft long with a 945 horsepower engine and with coal consumption of only 20 tons per day, allowing it to steam to the Far East. By 1890 the *Orestes* was 4653 grt, with a 2600 horsepower engine, and by 1902 the *Keemun* was 9074 grt with a 5,500 hp twin triple expansion engine. Finally, the *Nestor* built in 1914 was 14,000 grt. This more or less defined the liner vessel, and sizes did not increase significantly for the next 40 years.

The liner trades were complicated by the need for multi-port loading and discharge as well as the need for the service operator to offer trans-shipment to other ports not served directly by the liner. These operations were expensive and made the job of stowing and discharging cargo more complicated than a simple tramping operation. The cargo manifest for the 2849 grt cargo liner SS *Scotia*, carrying 5061 tons of cargo, shown in Table 1.6, illustrates this point. On the voyage in question the ship loaded 28 different commodities in bags, bales, cases and casks.

By the 1950s there were 360 liner conferences in the deep-sea trades, each with between 2 and 40 members which regulated sailings and freight rates.[76] The new liner companies were highly visible organizations with offices or agencies in the ports they served. Companies such as P&O, Blue Funnel, and Hamburg Süd became household names. Their prestigious office buildings housed teams of administrators, naval architects and operations staff who planned and directed fleets of a hundred ships or more as

they plied back and forth on their trades. Naturally the ships were registered locally, and the companies were generally publicly quoted, even though the stock was usually held by family members. In short, liner shipping became a prominent and highly respectable business, and young men joined the industry confident in the knowledge that they were serving national institutions.

Tramp shipping and the global market place

The other component in the nineteenth-century sea transport system was tramp shipping, a very different business. Tramps filled the gaps in the transport system, carrying the bulk and general cargoes not catered for by the liner services. They were the direct descendants of Captain Uring, working from port to port carrying grain, coal, iron ore, and whatever was available. However, they had two important advantages which made them much more efficient than their eighteenth-century counterparts. First, they were steamships, usually with a 'tween deck for stacking cargo, offering speed and flexibility. Second, through the cable system they had access to the Baltic Exchange, so they could fix cargoes ahead without waiting or making speculative ballast voyages as Captain Uring had to do.

The growth of the Baltic Exchange was a response to the high cost and inflexibility of the early cable network. In 1866 a transatlantic cable cost 4*s*. 3*d*. (about $1.25) per word.[77] To put that in perspective, in 1870 a seaman earned about $12.50 (£2 2*s*.) a month.[78] Although rates soon fell, in 1894 communicating with outlying areas such as South and East Africa still cost over $1.25 per word. This favoured a central market place where cargoes could be 'fixed' by local brokers and agents and the terms communicated to their clients by cable. London was at the heart of the cable network and the Baltic exchange became the market place where trade was done. The Virginia and Baltic Coffee House had been a popular shipping venue for a century, in 1744 advertising itself as the place 'where all foreign and domestic news are taken in; and all letters or parcels, directed to merchants or captains in the Virginia or Baltic trade will be carefully delivered according as directed and the best attendance given'.[79] By 1823 it had a committee, rules and an auction room where tallow was traded,[80] and when cables arrived in the 1860s it rapidly became the trading floor for the world tramp fleet.

Brokers circulated details of ships and cargoes at the Baltic, struck deals and cabled the terms to their principals in the briefest possible form.

London shipbroking companies were the intermediaries in the system.[81] The history of H. Clarkson & Co. Ltd records that in the 1870s Leon Benham, the company's leading broker, 'was in constant attendance at the Baltic Exchange. Several times a day he would return to the office to despatch telegrams, invariably drafted from jottings on the stiff cuff of his shirt'.[82] In 1869 Clarksons spent more on telegrams than on wages.[83] The Baltic reached a peak in 1903 when it opened the new exchange building in St Mary Axe. As long as international messaging remained cumbersome and expensive the Baltic was guaranteed a position as the global clearing house for shipping business.[84]

The shipping companies which operated in the tramp market were very different from the liner companies, though there was some overlap. Large tramp companies would sometimes establish liner services if they spotted a gap in the market and the liner companies sometimes engaged in 'tramping'. However, most of the tramp business was carried on by small companies. In 1912 over a third of the British tramp companies had only one or two ships, and by 1950 this had increased to more than half (Table 1.7). These businesses were often very small, relying heavily on outsourcing various skilled tasks. For example, marine and engineering superintendents were now available in most ports to deal with tech-

nical matters such as breakdowns and dry dockings; shipbrokers and agents chartered the ships for a commission; and chandlers provided deck and engine stores and victuals. Bunkers were readily available at advertised prices; crewing agencies supplied officers and crews; and insurance brokers and protection and indemnity (P&I) clubs were available to cover the various risks. In these circumstances a tramp owner really could 'carry his office under his hat'.[85] Some ships were owned by the captain or a syndicate using the system whereby the holding company was split into 64 shares (see Section 7.2).

Although the British were initially the biggest tramp owners, towards the end of the nineteenth century the Greek shipowners, who had built up thriving cargo shipping businesses on the commerce of the Black Sea and the Mediterranean, started to set up offices in London.[86] Soon they became an important part of the international tramp shipping scene. The Norwegians took a while to move from sail to steam and were less in evidence. Operating fleets of multi-deck vessels, these owners worked from port to port, carrying whatever cargoes became available, though by the early twentieth century they were mainly carrying bulk commodities. The breakdown of cargoes in

Table 1.8 British deep-sea tramp shipping cargoes, 1935

Cargo	Voyages	Cargo tons
Coal and coke	1,873	12,590,000
Grain	1,200	8,980,000
Grain and timber	105	890,000
Timber	196	1,345,000
Timber and other cargo	19	110,000
Ore	398	2,830,000
Fertilizers	207	1,535,000
Sugar	204	1,425,000
Other cargoes	610	3,785,000
Totals	4,812	33,490,000

Source: Isserlis (1938).

Table 1.8 shows that by 1935 coal and grain accounted for two-thirds of the tonnage of cargo shipped, with timber, ores, fertilizers and sugar making up another quarter.

A typical tramp itinerary in the 1930s illustrates how the tramp business worked. The ship was chartered to carry rails from Middlesbrough to Calcutta. From there it loaded jute gunny-bags for Sydney, then ballasted to Newcastle, NSW, to load coal for Iquiqui in Chile, expecting to load nitrate. However, there were many ships waiting in the nitrate ports, so instead, after an exchange of cables, the ship ballasted to the River Plate where the maize harvest would soon be coming forward and demand was expected to be brisk. However, by the time the ship reached Buenos Aires many ships had recently arrived with coal from Britain and were looking for a backhaul, so supply exceeded demand. After waiting a couple of weeks it was eventually fixed at a slightly higher rate by a maize trader with an option to discharge in London, Rotterdam or Genoa, for each of which a freight was specified. The ship was to call for orders at St Vincent in the Cape Verde Isles, where the master learned he was to proceed to Rotterdam, then load coal for Genoa. From Genoa he was instructed to proceed to Algeria and load iron ore for the Tees. The permutations were endless, but at each stage owners and shipbrokers worked furiously to find the best cargo for the next leg and cable instructions to the ship's master and it is easy to see why the Baltic Exchange played such an important part in coordinating the activities of the tramp fleet.[87]

When not tramping, tramp ships would often be chartered to cargo liner companies in need of extra capacity, thus providing a link between the bulk and liner businesses. This was possible because both segments of the market used similar ships. Generally the tramp operators invested in basic multi-deck vessels of between 5,000 and 10,000 dwt, with a 'tween deck to stack general cargo and bottom holds designed to carry bulk. Some more expensive tramps were designed with liner charters in mind, with a slightly faster speed and special features such as refrigerated holds, deep well tanks to carry vegetable oils, cabins for 20 or more passengers and heavy lift cranes for awkward cargoes. However, the basic tramp design was instantly recognizable.

Regulation of shipping

As the volume of business increased so did the framework of regulations imposed by the insurance industry. In the eighteenth century the London insurance industry
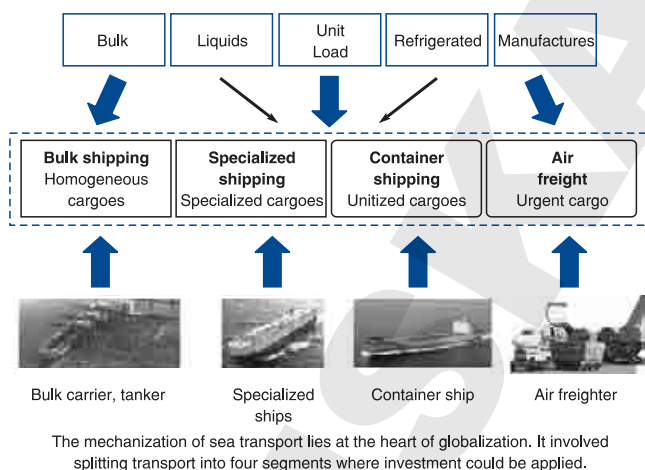

developed a system to check that the ships they insured were soundly built and in good condition. By the early nineteenth century Lloyd's Register, which had started life in the 1760s as a register of ships, had assumed the role of setting standards and issuing classification certificates. After a major reorganization in 1834, 63 surveyors were appointed and they made a complete resurvey of the 15,000 ships in the Register. Any new vessel for which an A1 classification was sought must undergo 'a survey under construction', which meant in practice that its progress was closely inspected at least three times while its hull was on the stocks. In 1855 Rules for Iron Ships were issued by the Society, and subsequently committees were established to set construction standards for new ships and the network of surveyors monitored their implementation. Several other countries set up classification societies, among them the American Bureau of Shipping and Det Norske Veritas, and by the end of the nineteenth century the industry's technical regulatory system was in place.

Governments also became involved in regulating shipping, particularly the British government. After a series of scandals involving ships used in the emigrant trade, the Merchant Shipping Act 1854 was passed. This set out a legal framework for the registry of ships; tonnage measurement; survey of ships and equipment; carriage of dangerous goods; safety and seaworthiness of ships; protection of seamen; and inspection of provisions. From time to time it was extended, often in the face of opposition from the shipping industry; for example, the recommendation of the 1874 Royal Commission on unseaworthy ships that a load line (for many years known as the 'Plimsoll mark') should be introduced to prevent ships being overloaded was opposed by British owners who complained it would give them an unfair disadvantage. The body of maritime laws developed at this time, when Britain controlled half the world merchant fleet, was used by many other countries as the template for enacting their own maritime law providing the basis for a maritime legal system which was reasonably consistent between countries. The first formal step in this direction was the Law of the Sea conference held in Washington in 1896, listing an agenda of items to regularize shipping activities.

1.6 CONTAINER, BULK AND AIR TRANSPORT, 1950–2006

The rationale for sea transport integration

By 1950 the liner and tramp system had worked successfully for a century and it was hard to believe that it could suddenly disappear, but that is exactly what happened. Although it was immensely flexible, it was far too labour-intensive to survive in the post-1945 global economy where rising labour costs made mechanization inevitable. This meant replacing expensive labour with cheaper capital equipment and increasing the size of transport operations to take advantage of economies of scale.[88] As a result, 30 years later there was nothing left of the proud, conservative shipping industry which sailed confidently into the 1950s. The passenger liners disappeared in a decade, or were converted into cruise ships, and the cargo liners and tramps were gradually replaced by

SEA TRANSPORT AND THE GLOBAL ECONOMY

The mechanization of sea transport lies at the heart of globalization. It involved splitting transport into four segments where investment could be applied.

Figure 1.10
The bulk and container shipping system after 1950

the new transport systems illustrated in Figure 1.10, using technology already well established in land-based industries such as car manufacture. The new system reduced costs by replacing expensive labour with cheaper and more efficient capital equipment and by treating sea transport as part of an integrated through-transport system. Standardization, automation of cargo handling, economies of scale, and developing ship designs adapted for efficient cargo stowage and handling all played a part in this process.

Homogeneous bulk cargoes were now carried by a fleet of large bulk carriers operating between terminals designed to mechanize cargo handling; general cargo was containerized and transported by a fleet of cellular container-ships; and five new specialized shipping segments evolved to transport chemicals, liquefied gases, forest products, wheeled vehicles, and refrigerated cargoes, each with its own fleet of specially designed ships. One side effect of automation was that shipping, which had previously been one of the world's most visible industries, became virtually invisible. The busy ports with miles of wharves were replaced by deserted deep water terminals handling cargo in hours, not weeks, and the shipping companies which had become household names were replaced by independent shipowners operating under 'flags of convenience'.

Many factors contributed to these changes. The airlines took over the passenger and mail trades from the passenger liners and the European empires were dismantled, removing two of the liner companies' most important revenue streams. American, European and Japanese multinationals relying on imported raw materials actively encouraged the new bulk shipping industry by offering time charters, and with this security it was easy to access investment funds from the emerging eurodollar market. Improved communications, including telex, fax, direct-dial phone calls and later e-mail and cheap inter-regional air travel, all helped to create an even more efficient global market place for shipping services. Thus the foundations were laid for a more efficient shipping business, combining economies of scale with an unprecedented ability to apply technology and logistics to the ever-changing pattern of seaborne trade.

The new trade environment created at Bretton Woods

The change started with the new trade strategy adopted by the Western nations after the Second World War. Since the early 1940s the United States had been determined that

after the war the restrictions of the colonial system should be removed, providing free access to global markets and raw materials. In July 1941 a memorandum from the US Council on Foreign Relations argued that to achieve this, the world needed financial institutions capable of 'stabilising currencies and facilitating programmes of capital investment in backward and underdeveloped regions'.[89] At the Bretton Woods Conference in 1944 the US Secretary of the Treasury, Henry Morgenthau, outlined the objective of creating 'a dynamic world economy in which the peoples of every nation will be able to realise their potentialities in peace and enjoy increasingly the fruits of material progress of an earth infinitely blessed with natural riches'.[90] By the end of the meeting the World Bank and the International Monetary Fund had been founded and the groundwork had also been laid for the General Agreement on Tariffs and Trade (GATT).

This policy had a profound effect on the maritime industry. By the end of the 1960s almost all of the European colonies had been given independence and they were encouraged to open their borders and transform their economies from self-sufficiency to export production. Trade agreements negotiated through GATT opened economies in both North and South to the free movement of goods and money. Capital flows were liberalized and multinational corporations systematically developed raw materials, manufacturing capacity and local consumer markets. Since the whole system depended on trade, efficient shipping played a central part in creating this new global economy and the imperially based liner system was not well positioned to meet the needs of the new order.
Growth of air transport between regions

During the same period the airlines became serious competitors for the passenger and mail markets, one of the mainstays of the liner system. In 1950 ships still carried three times as many passengers across the Atlantic as aircraft, and in 1952 Cunard-White Star had nine vessels in the New York trade, with another four working out of Southampton to Canadian ports.[91] However, with the arrival of passenger jets the economics moved decisively in favour of the airlines. A passenger liner needed 1,000 crew and 2,500 tons of fuel to deliver 1,500 passengers to New York once a week. Even a first-generation jet carrying 120 passengers could make eight or nine crossings in a week, delivering almost 1,000 passenger crossings, but with only 12 crew and burning only 500 tons of fuel.[92] The flight time of 6 hours was an added bonus for busy travellers. On these economic considerations there was no contest. In 1955 almost 1 million passengers crossed the Atlantic by sea and about 750,000 by air, but by 1968 over 5 million travelled by air but only 400,000 by sea.[93] When jumbo jets arrived in 1967 the longer routes followed, and between 1965 and 1980 air traffic increased from 198 billion passenger kilometres to 946 billion.[94]

The last great passenger liner, the *Queen Elizabeth 2*, was ordered at John Brown's shipyard on Clydeside in 1963 as a dual-purpose passenger and cruise vessel for the Atlantic service, but two years after it was delivered in 1968 the jumbo jets came into service and it mainly served as a cruise liner. The passenger liners of the 1950s, built for speed, either went to the scrapyard or were converted into cruise liners offering a

mobile leisure environment in which speed is irrelevant, bringing to an end the era of the great passenger liner.

Growth of seaborne trade, 1950–2005

Meanwhile sea trade was growing faster than at any time since the early nineteenth century, with imports increasing from 500 million tonnes in 1950 to 7 billion tonnes in 2005 (Figure 1.11). This growth was led by Europe and Japan. Both had been badly damaged during the war, and set about the reconstruction of their economies. Released from their colonial empires, the European multinationals set about post-war reconstruction. Expansion of heavy industries such as steel and aluminium, combined with the substitution of imported oil for domestic coal in power stations, railway locomotives and rising car ownership, produced rapidly growing imports, particularly of bulk commodities. This growth persisted through the 1960s and the upward trend in imports was reinforced by the switch from domestic to imported sources for key raw materials such as iron ore, coal and oil. By the early 1970s the European economy was maturing and demand for raw material intensive goods such as steel, aluminium and electricity stabilized.

The growth of Japan followed a similar pattern, but changed the focus of world shipping, because it was the first major industrial economy in the Pacific region. Development had started in the late nineteenth century, but after 1946 the Japanese economy was reorganized and the 'trading houses' took over the traditional coordinating role of the *zaibatsu*. Leading industries such as shipbuilding, motor vehicles, steel and shipping were selected by the Ministry of International Trade and Industry which coordinated growth for development, and during the 1960s the Japanese economy embarked upon a programme of growth which made it the world's leading maritime nation. Between 1965 and 1972 Japan generated 80% of the growth of the deep-sea dry cargo trade, and by the early 1970s it built half the world's ships and, taking account of open registry vessels, controlled the world's largest merchant shipping fleet.

In the 1970s the two oil crises coincided with the end of the European and Japanese growth cycle and the lead in trade growth switched to the Asian economies – notably

South Korea, which embarked on a programme of industrial growth. Emulating Japan, it rapidly expanded its heavy industries such as steel shipbuilding and motor vehicles. Then, in the 1980s, after two decades of total isolation and many centuries of restricted contact with the West, the Chinese economy opened its doors to capitalism and trade. There followed a period of remarkable economic growth, coupled with a move towards a more Westernized capitalist economic system.

The world economy was entering a new consumer-driven era, and during the 1960s the flow of motor cars, electronic products and a host of others increased very rapidly and the framework of trade widened, bringing in Asian economies and a more extensive trade with Africa and South America. This turned sea trade into a complex network connecting the three industrial centres in the temperate latitudes of the Northern Hemisphere – North America, western Europe and Japan – which generated about 60% of the trade, and drawing in raw materials and exporting manufactures.

Shipping's 'industrial revolution'

Trade expansion on this scale would not have been possible without a major reform of the transport system. The new transport model that emerged gradually over 20 years had the three segments shown in Figure 1.10: bulk shipping, specialized shipping and containerisation. During the next 35 years many new ship types were developed, including bulk carriers, supertankers, liquefied gas tankers, chemical tankers, vehicle carriers, lumber carriers and, of course, container-ships.

The development of bulk transport systems

The new bulk shipping industry was mainly masterminded by the multinationals, especially the oil companies and steel mills. Until the early 1950s the oil trade was still quite small and oil was mainly shipped as products in small tankers. However, as markets grew the strategy changed to shipping crude in large volumes to refineries located near the market, and this allowed bigger ships to be used (see Section 12.2). At the same time the steel mills were moving to coastal sites and developing overseas iron ore and coalmines to supply them. For the new generation of bulk carriers constructed for this trade, the only restrictions on size were the size of cargo parcels and the depth of water at the terminals, both of which increased rapidly. Commodities like oil, iron ore and coal were used in sufficiently large quantities to make cargo parcels of 100,000 tons or more practical and cargo shippers built deep-water terminals with automated cargo-handling systems. By investing in big ships and high-speed cargo-handling systems, it was decisively cheaper to import raw materials by sea from suppliers thousands of miles away than by land from suppliers only a few hundred miles away – for example, the rail freight for a ton of coal from Virginia to Jacksonville, Florida, was almost three times the sea freight from Hampton Roads to Japan, a distance of 10,000 miles.

Tankers illustrate the evolution in ship size (Figure 1.12). The 12,500 dwt *Narraganset* was built in 1903, and this remained a very acceptable size of vessel until 1944 when the largest tanker was the *Phoenix* of 23,900 dwt. During the Second World War the T2
Figure 1.12
Average size of tanker, 1900–2005

tanker, a 16,500 dwt vessel, had been mass-produced, and that remained the workhorse size, mainly shipping products from refineries based near the oil-fields. Then in the 1950s tanker sizes started to increase. By 1959 the largest tanker afloat was the *Universe Apollo* (122,867 dwt), and in 1966 the first very large crude carrier (VLCC), the *Idemitsu Maru* 209,413 dwt followed, just two years ahead of the *Universe Ireland* (326,585 dwt) the first ultra large crude carrier (ULCC) in 1968. This upward trend peaked in 1980 when the *Seawise Giant* was extended to 555,843 dwt. Overall the increase in ship size probably reduced unit shipping costs by at least 75%.

In dry bulk shipping, the move into large bulk vessels was equally pronounced. Although 24,000 dwt ore carriers were used in the 1920s, in 1950 most bulk cargo was still carried in tramps of between 10,000 and 12,000 dwt. The move to bigger ships followed the same pattern as tankers, and by the 1970s vessels of 200,000 dwt were widely in use on the high-volume routes, while the first generation of 300,000 dwt vessels started to come into service in the mid-1980s. There was also a steady upward movement in the size of ships used for the transport of commodities such as grain, sugar, non-ferrous metal ores and forest products. Taking the grain trade as an example, in the late 1960s most of the grain shipped by sea was in vessels under 25,000 dwt.[95] It seemed inconceivable to shippers in the business that vessels of 60,000 dwt could ever be used extensively in the grain trade, although by the early 1980s this is precisely what had happened.

Technical improvements, though less dramatic than previously, were significant. Hatch designs, cargo-handling gear and navigation equipment all improved in efficiency. During the 1980s the fuel efficiency of diesel engines increased by 25%. Shipbuilders became more adept at fine-tuning hull designs, with the result that for some ship types the steel weight was reduced by 30%; hull coatings improved to give the submerged hull better smoothness and improved longevity for tank structures.

Bulk shipping also benefited from improving communications. During this period the position of the Baltic Exchange as a central market for shipping was undermined by improved communications including direct-dial telephony, broadcast telex, fax and e-mail. It was no longer necessary to meet face-to-face to fix ships. Instead owners,

brokers and cargo agents used telex messages to distribute cargo/position lists and negotiations were handled by phone. In the 1970s computerized work stations allowed telex or fax messages to be sent by the user and also provided access to databases of ship positions, vessel details and voyage estimating programs. PC networks, which appeared in the 1980s, made these facilities available cheaply to even the smallest companies, and modems gave access to the office workstation from home. The final link in the virtual market place was the cellular telephone, which allowed a broker to go out for lunch even while he was 'working' a ship – now that really *was* progress!

As the fleet of tankers and bulk carriers grew and the independent owners became more established, the multinationals gradually reduced their owned and chartered fleets, relying more on independent shipowners and the rapidly growing charter market. As information technology improved in the 1970s, the market started to segment by ship type – VLCCs, products tankers, Handy bulkers, Panamax, Capesize, chemicals, etc. Teams of specialist brokers developed an in-depth knowledge of their sector – its ships, charterers, ports and cargoes – and combined this with the 'soft' information gained from daily networking to gain negotiating leverage. By allowing market specialization, cheap, fast communications took the business a step forward in terms of logistic efficiency. The result was the highly efficient transport system for bulk cargoes we have today.

The containerization of general cargo

Developing a new system for shipping general cargo was left to the shipowners and it took much longer to get started. By the 1960s congested ports and labour difficulties were slowing transit times, and cargo shipped from Europe to the United States took months to arrive. Industry observers could see that 'the old methods had reached the end of the line',[96] but the way forward was not obvious. The problem facing the liner companies when they finally started to investigate unitization in 1960 was that liners had always been flexible in the cargo they carried and some cargoes were difficult to containerize. Containerization, which excluded all cargoes that would not fit in a standard 20-foot box, seemed an extreme solution, and even in 1963 the debate was not resolved. Companies experimented with flexible systems such as cargo palletization and ro-ro ships, which combined unitization with the flexibility to carry bulk cargoes like forest products. But in reality containerization was not just about ships. It was a completely new way of organizing transport, involving massive capital investment and an end to the control of trade by separate shipping companies working within a closed conference system.[97] The first transatlantic service was started on 23 April 1966 by Sea-Land, a new US company which had been developing the concept since 1956 (see Chapter 13). Transporting general cargo in standard boxes had a more fundamental impact than even its most ardent advocates anticipated. Just a few days after leaving the factory in the Midlands of England, a container wagon could be arriving at its destination in East Coast USA with its cargo safe from damage or pilferage and readily transferable to rail or barge with the minimum of delay and effort. By adopting containerization the industry opened the floodgates for global commerce (see Chapter 12 for more history).

Containerization was made possible by developments in communications and information technology. Until the 1960s, liner services were very fragmented, and managers in one service knew little of what was going on in others. When containerization arrived in the 1960s, the pendulum swung to the other extreme because it 'could not have been accomplished without computer control systems for controlling the movement of containers, taking bookings, printing out bills of lading and invoices and transmitting advice and information'.[98] Only large companies could afford the mainframe computer systems needed to run a container service, so 'the dominance of the mainframe computer, development of data bases and rationalisation of systems predicated central control for a major operator'.[99] By the mid-1990s the system for handling containers had become very sophisticated and was squeezing more value out of the transport business, pioneered by operators such as OCL in the 1970s. These developments were immensely productive, reducing cycle times by 40%, errors by 30% and saving $5 per document.[100] This was a great leap forward for those big enough to be able to afford it.

Transport of specialized cargoes

Some cargoes did not fit comfortably in either the container or the bulk shipping systems, and gradually specialized shipping services developed to carry them. The five commodity groups which became the focus for specialized shipping operations were: forest products; chemicals; refrigerated cargo; cars and wheeled vehicles; and liquefied gases. Previously these had all been carried in liners or tramps, often with the help of some special investment such as refrigerated holds and deep tanks for liquid chemicals and vegetable oil. However, the standard of service was often poor. For example, vehicles were very expensive to transport and were often damaged in transit. As the volume of these cargoes grew, shippers and owners often worked together to improve the economics of the service, creating a period of tremendous innovation in ship design. From 1950 onwards the innovations came thick and fast. The first chemical parcel tanker, the *Marine Dow Chem* was built in the United States in 1954, and this was soon followed by the first container-ship, a conversion, in 1956. In the same year Wallenius lines built the first car carrier, the *Rigoletto*, designed for the carriage of 260 cars, and the first open hatch bulk carrier, designed with wide hatches to carry pre-packaged timber was built in 1962, for use in the paper trade. The first purpose-built liquefied natural gas (LNG) tanker came in 1964 and the first liquefied petroleum gas (LPG) tanker in 1955.

Each of these pioneer ships eventually grew into a fleet, and a new business sector for the shipping industry arose. In most cases the mode of operation was dramatically different from the 'quayside to quayside' business of the preceding century. The defining feature of these specialized segments is that they focus on the transport of a single cargo which permits, or requires, specialist investment to improve efficiency. As a result, the ships are closely integrated with the industries they served, often a small group of charterers. Chemical tankers carried small parcels of chemicals between industrial plants; car carriers became an integral part of the international motor business; and LNG tankers are shuttled between specially built terminals. The investment and organization behind these projects created the new concept of

specialized shipping which became one of the building-blocks of the post-war global economy.

Changing shipping company organization

As the shipping industry changed, so did the companies that ran it. Out of the top 10 UK liner companies in 1960, none remained 50 years later and there were no tramp companies left. The change in registration is very apparent from the fleet statistics in Table 1.9. In 1950, 71% of the world fleet was registered in Europe and the United States, and 29% under overseas flags. By 2005 the share of the European and US flags had fallen to 11%, whilst other countries, particularly flags of convenience such as Liberia and Panama, accounted for 89%. Part of this change is explained by the growth of new economies, particularly Japan, South Korea and China, whose national fleets grew rapidly. For example, the Japanese fleet grew from 1.9 million grt in 1952 and 18.5 million grt in 1997. However, a more important explanation is the growing importance of independent shipowners in the post-Bretton Woods world and their preference for open registries such as Liberia and Panama as a way of reducing costs.

The independent shipowners of this new generation were descendants of the tramp operators who had served the liner companies for the last century, supplemented by a new generation of businessmen such as Onassis, Niarchos, Pao and Tung who saw the opportunities in shipping. As the established national shipping companies struggled to adapt, weighed down by wealth, tradition and the wrong ships, the 'tramp' operators of Norway, Greece and Hong Kong were quick to spot that their new clients were the

multinational oil companies, steel mills, aluminium producers, etc. These large companies needed the raw materials available in Africa, South America and Australasia, and that meant cheap sea transport. Whilst the established and cash-rich shipping companies were not attracted by this risky, low-return business, the independents were only too willing. Using time charters from the multinationals as security to raise finance, they rapidly built up the fleets of tankers, bulk carriers and specialized ships that were needed. Since the charters were subject to intense competition, to keep costs low they used an invention of American tax lawyers, the 'flag of convenience'. By registering the ships in a country such as Panama or Liberia, they paid only a fixed registration fee, and no further taxes were payable (see Chapter 16).

So once again the character of the shipping industry changed. The shipping companies were transformed from high-profile pillars of imperial respectability into intensely private businesses run by entrepreneurs. The change was compounded during the long recession of the 1980s (see Chapter 4) when even the most efficient shipowners had to 'flag out' and cut corners to survive. To the reputation for privacy was added the image of running ships that were 'old and corroded, structurally weak'.[101] By the 1990s governments, which had raised no real objection to the growth of the independent shipping industry during the earlier period, became concerned about the quality standards and the safety of the ships which operated in their national waters.

1.7 LESSONS FROM 5,000 YEARS OF COMMERCIAL SHIPPING

So that brings us to the end of the Westline. From the early sea trade in the Lebanon 5,000 years ago, the line has now arrived at China, and is heading through SE Asia to India, the Middle East, Central Asia, Russia and eastern Europe. The shipping industry has a unique opportunity to study its commercial history, and there are many lessons which we could draw, but three stand out.

The first is the central part which shipping has played in the global economy. At every stage in its development, sea transport has figured prominently, and the shipping industry, with its distinctive international flavour, has played a central role.

Second, the basic economics of the business have not changed all that much over the years. The messages gleaned from the Mesopotamian Maritime Code, the Roman bill of lading or even Captain Uring's exploits in the eighteenth century all tell the same story of a business driven by the laws of supply and demand. The ships, technology and customers change, but the basic principals of maritime commerce seem immutable. Although there is continuity in the economic model, the circumstances can change with remarkable speed. The break-up of the Roman Empire; the voyages of discovery in the sixteenth century, steam and the colonial system in the nineteenth century, and the mechanization of shipping in the second half of the twentieth century all dramatically changed the world in which shipowners operated. In the process, shipping today has become more than ever before an integral part of the process of globalization.

Third, shipping prospers during periods of political stability when the world is prosperous and stable. For example, we saw how the Mediterranean trade prospered

when the Roman Empire provided safe passage, and declined when the *Pax Romana* broke down in the third century. Similarly the stability provided by the European empires from 1850 to 1950 created a framework in which the liner and tramp system could operate. Then a new period of globalization in the post-Bretton Woods era following the Second World War did the same sort of thing and once again the shipping business had to adapt. So the lesson is that the starting-point for any future analysis is not economics but the geopolitical environment and where that is going.

But change was not always gradual. The step changes in knowledge and technology were often followed by longer transitional periods as the commercial infrastructure was developed to put the changes into practice. As a result, revolution was softened into a more gradual evolution. Thus the voyages of discovery at the end of the fifteenth century took just a couple of decades, but it took centuries for the new global commercial trading system to grow out of them. Similarly, the transition from sail to steam started in the 1820s but it was almost a century before steamships had completely taken over merchant shipping from sail. More recently, containerization started in the 1950s but it was 25 years before its full potential as a global transport system was felt in world trade. So although change is sudden, the implementation of change is often a long and tedious business.

Pulling all this together, our task as maritime economists is to understand where we are at any point of time, so that we can see where things might go next. We must also understand the evolutionary nature of change. The die may be cast, but it is often many years before the real consequences of change become apparent. Today we are in a phase of transition created by globalization which is, in its own way, as revolutionary as the voyages of discovery five hundred years ago.

1.8 SUMMARY

In this chapter we examined how shipping developed over the last 5,000 years. It turns out that today's trade network is just a snapshot taken as the world economy creeps jerkily along its evolutionary path. The pace is usually too slow for contemporaries to see the trend, but from a historical perspective the progress is evident. The central role of shipping in this process was obvious to early economists such as Adam Smith, who recognized that shipping offers the transport needed to promote economic development. Indeed, shipping, trade and economic development all go hand in hand.

We divided the history of trade into three phases. The first started in the Mediterranean, spreading west through Greece, Rome and Venice, to Antwerp, Amsterdam and London. During this phase a global trading network gradually developed between the three great population centres in China, India and Europe. At first this trade was by land and was slow and expensive, but when the voyages of discovery opened up global sea routes in the late fifteenth century, transport costs fell dramatically and trade volumes escalated.

The second phase was triggered by the industrial revolution in the late eighteenth century. Innovations in ship design, shipbuilding and global communications made it possible for shipping to be conducted as a global industry, initially through the Baltic Exchange, whilst reliable steamships and technical innovations such as the Suez Canal

made it possible for liner companies to operate regular services. For the next century trade grew rapidly, focused around the colonial empires of the European states and the framework of sea trade was radically changed.

Finally in the second half of the twentieth century another wave of economic and technical change was triggered by the dismantling of the colonial empires which were replaced by the free trade economy initiated at Bretton Woods. Manufacturers set out to track down better sources of raw materials and invested heavily in integrated transport systems which would reduce the cost of transporting these goods. During this period we saw the growth of the bulk carrier markets, the containerization of general cargo and specialist shipping operations transporting chemicals, forest products, motor vehicles, gas, etc. An important part of this revolution was the move of shipping away from the nation states which had dominated previous centuries towards flags of convenience. This brought greater economies and changed the financial framework of the industry, but it also raised regulatory problems.

The lesson is that shipping is constantly changing. It is a business that grew up with the world economy, exploring and exploiting the ebb and flow of trade. Today it has become a tightly knit global business community, built on communications and free trade. Perhaps that will change. But it is hard to disagree with Adam Smith that, whatever the circumstances 'such therefore are the advantages of water transport that … this conveniency opens the whole world to the produce of every sort of labour'.[102]
